Neurotransmitters and Synapses. STUDY. PLAY .  
Excitatory synapses. The neurotransmitter released by the presynaptic neuron causes sodium ions or other positively charged ions to enter the postsynaptic neuron, helping to depolarise it and cause an action potential. Postsynaptic transmission is therefore excited (stimulated). Inhibitory Synapses. The neurotransmitter released by the presynaptic  
Chapter 11 - Synapse & Neurotransmitters Questions and ...  
Repeated or continuous use of a synapse enhances the presynaptic neuron's ability to excite the postsynaptic neuron, producing larger than expected postsynaptic potentials Presynaptic Inhibition It occurs when the release of excitatory neurotransmitter by one neuron is inhibited by the activity of another neuron via an axoaxonic synapse

Synapses are the places where action potentials are passed from one neuron to the next. Post-synaptic neurons are stimulated by many different pre-synaptic neurons, some excitatory and some inhibitory.  
What are the differences between excitatory and inhibitory ...  
Typically it is the neurotransmitter contents at the level of synapses that determines whether the neuron is excitatory or inhibitory. For example, neurons that express the neurotransmitter glutamate are excitatory, those that express the neurotransmitter GABA are inhibitory.  
Synapses - biology-pages.info  
The junction between the axon terminals of a neuron and the receiving cell is called a synapse. (Synapses at muscle fibers are also called neuromuscular junctions or myoneural junctions. ) Action potentials travel down the axon of the neuron to its end(s), the axon terminal(s).

Key Difference Excitatory vs Inhibitory Neurotransmitters  
Neurotransmitters are chemicals in the brain which transmits signals across a synapse.

[Difference Between Inhibitory and Excitatory | Difference ...](#)

Synapses are junctions that allow a neuron to electrically or chemically transmit a signal to another cell. Synapses can either be excitatory or inhibitory. Inhibitory synapses decrease the likelihood of the firing action potential of a cell while excitatory synapses increase its likelihood.

Excitatory synapses cause a positive action potential in neurons and cells. For example, in the

[Inhibitory postsynaptic potential - Wikipedia](#)

The opposite of an inhibitory postsynaptic potential is an excitatory postsynaptic potential (EPSP), which is a synaptic potential that makes a postsynaptic neuron more likely to generate an action potential. IPSPs can take place at all chemical synapses, which use the secretion of neurotransmitters to create cell to cell signalling.

Inhibitory presynaptic neurons release neurotransmitters that then bind to the

Actions of Excitatory and Inhibitory Neurotransmitters.  
Some neurons in the CNS release neurotransmitters that excite other neurons (meaning to fire off APs) and some inhibit (prevent) the generation of action potentials. Action of Excitatory Neurotransmitters. Presynaptic neurons are the neurons that conduct the AP to release a neurotransmitter and they affect the postsynaptic neurons. What

Factors that control differentiation of presynaptic and postsynaptic elements into excitatory or inhibitory synapses are poorly defined. Here we show that the

postsynaptic density (PSD) proteins PSD-95 and neuroligin-1 (NLG) are critical for dictating the ratio of excitatory-to-inhibitory synaptic contacts.

#### Neuron - Wikipedia

A neuron, also known as a neurone (British spelling) and nerve cell, is an electrically excitable cell that communicates with other cells via specialized connections called synapses. All multicellular organisms except sponges and *Trichoplax* have neurons.
